# On Higher Dimensional Perfect Factors 

Glenn Hurlbert ${ }^{1}$<br>Garth Isaak ${ }^{2}$<br>2/27/95

Abstract. A d-dimensional Perfect Factor is a collection of periodic arrays in which every $k$-ary $\left(n_{1} \times \cdots \times n_{d}\right)$ matrix appears appears exactly once (periodically). The one dimensional case, with a collection of size one, is known as a De Bruijn cycle. The 1- and 2-dimensional versions have proven highly applicable in areas such as coding, communications, and location sensing. Here we focus on results in higher dimensions for factors with each $n_{i}=2$.

## 1. Introduction.

A d-dimensional $k$-ary, order $\vec{N}$ perfect factor of size $t$ and period $\vec{R}$ (called a De Bruijn family in [13]) is a family $\left\{B_{1}, \ldots, B_{t}\right\}$ of $d$-dimensional $k$-ary (entries from a $k$ element set, typically $[k]=\{0,1, \ldots, k-1\}$ ) toroidal (i.e. periodic) arrays, of period $\vec{R}$ each, with the property that for every $d$-dimensional $k$-ary matrix $M$ of order $\vec{N}$ there is a unique $j$ and a unique $\vec{I}$ so that $M$ appears in $B_{j}$ at position $\vec{I}$. (We will say that a particular matrix $M$ of size $\vec{N}$ appears in $B$ at position $\vec{I}=\left\langle i_{1}, \ldots, i_{d}\right\rangle$ if $M$ appears in the positions $\vec{I}$ through $\vec{I}+\vec{N}$.) We call such a perfect factor a $(\vec{R} ; \vec{N} ; t)_{k}^{d}$ perfect factor and denote the set of all such perfect factors by $P F_{k}^{d}(\vec{R} ; \vec{N} ; t)$.

In the case that $d=t=1$, perfect factors have been called De Bruijn cycles. Perfect factors with $t=1$ and $d>1$ have been called de Bruijn tori and perfect maps. It has become clear in past work that the existence of perfect factors greatly facilitates the construction of De Bruijn tori. See [13] for more details (or [17] for the two-dimensional case). The De Bruijn graph $d B(n, k)$ is defined as follows. It's vertex set consists of all $k$-ary $n$-tuples, and there is a directed arc from $x_{1} \ldots x_{n}$ to $y_{i} \ldots y_{n}$ whenever $y_{i}=x_{i+1}$ for each $i<n$ (see figure 1). The term 'factor' comes from the fact that when $d=1$ the fundamental blocks of a $k$-ary order $n$ perfect factor of period $r$ actually give rise to a factoring of the arcs of $d B(n-1, k)$ into cycles of length $r$, since the arcs of $d B(n-1, k)$ correspond to the vertices of $d B(n, k)$.

[^0]Figure 1. $d B(3,2)$.
For example, $F=\{(000111),(01)\}$ factors the arcs of $d B(2,2)$ into two cycles, but they are of different lengths and so $F$ is not a perfect factor. However, we do have that $\{(0001),(0111)\} \in P F_{2}^{1}(4 ; 3 ; 2)$. Likewise, if

$$
A=\begin{array}{|cc|}
\hline 0 & 0 \\
0 & 1
\end{array} \quad \text { and } \quad B=\begin{array}{|ccc|}
\hline 0 & 0 & 1 \\
0 & 0 & 1 \\
1 & 1 & 0 \\
1 & 1 & 1 \\
\hline
\end{array}
$$

then every binary $2 \times 2$ matrix occurs exactly once in either $A$ or $B$, exclusively. But $\{A, B\}$ is not a perfect factor since $A$ and $B$ are of different sizes. However, for the torus $C$ below, we have that $C \in P F_{2}^{2}(4,4 ; 2,2 ; 1)$.

$$
C=\begin{array}{|llll|}
\hline 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
1 & 0 & 1 & 1 \\
0 & 1 & 1 & 1 \\
\hline
\end{array}
$$

De Bruijn cycles were first discovered in [7] and later independently in [2] and [9] (see Frederickson [8] for a survey of De Bruijn cycles). 2-dimensional De Bruijn tori are examined in [1,4-6,11-18], among others. A 2-dimensional De Bruijn torus $\left(r_{1}, r_{2} ; n_{1}, n_{2} ; 1\right)_{k}^{2}$ is square if $r_{1}=r_{2}=r$ and totally square if $n_{1}=n_{2}=n$ as well. It was asked in [3] whether such totally square tori exist. Except for small values of $n_{j}$, it has been shown (see [6] for $k=2$ and [11] for general $k$ ) that the obvious necessary conditions $r>n$ and $r^{2}=k^{n^{2}}$ are also sufficient for their existence.

We have conjectured [11] (as others have) that for general De Bruijn tori, the necessary conditions $r_{j}>n_{j}$ and $R=k^{N}\left(R=\Pi r_{j}, N=\Pi n_{j}\right)$ are also sufficient, except possibly for some "small" cases. Etzion [5] gave constructions for De Bruijn tori in $P F_{2}^{2}\left(2^{t}, 2^{n_{1} n_{2}-t} ; n_{1}, n_{2} ; 1\right)$ for all $n_{1}<2^{t} \leq 2^{n_{1}}$, except $n_{1}=t$ and $n_{2}=2$, and for all $n_{1}<2^{t} \leq 2^{n_{1}-1}$ when $n_{2}=2$.

Paterson [16] finished off the 2-dimensional binary case, proving that $P F_{2}^{2}\left(r_{1}, r_{2} ; n_{1}, n_{2}\right.$; $1) \neq \emptyset$ if and only if $r_{i}>n_{i}$ and $r_{1} r_{2}=2^{n_{1} n_{2}}$. Paterson [18] has recently extended this result to arbitrary base $k$, showing that the necessary conditions $r_{i}>n_{i}$ and $r_{1} r_{2}=k^{n_{1} n_{2}}$ are nearly sufficient for the existence of De Bruijn tori in $P F_{k}^{2}\left(r_{1}, r_{2} ; n_{1}, n_{2} ; 1\right)$. His constructions miss
the cases when $k, r_{1}$ and $r_{2}$ have prime factorizations $k=\prod_{j=1}^{s} p_{j}^{\alpha_{j}}, r_{1}=\prod_{j=1}^{s} p_{j}^{\beta_{j}}$ and $r_{2}=\prod_{j=1}^{s} p_{j}^{\gamma_{j}}$ with either $p_{j}^{\beta_{j}}<n_{1}$ or $p_{j}^{\gamma_{j}}<n_{2}$ for each $j \leq s\left(P F_{30}^{2}\left(30,30^{11} ; 6,2 ; 1\right)\right.$ and $P F_{6}^{2}\left(2^{9}, 3^{9} ; 3,3 ; 1\right)$, for example).

As for the base a power of two, we proved in [12] that, for all $s$ and $t, P F_{2 s t}^{2}\left(4 s t^{2}, 4 s^{3} t^{2} ; 2\right.$, $2 ; 1) \neq \emptyset$, extending the techniques of [14]. Implicitly, we proved in that paper that $P F_{2 s t}^{2}\left(4 s t, 4 s t ; 2,2 ; s^{2} t^{2}\right) \neq \emptyset$, which, because of the way in which we proved they could be linked together, implies that, for all $\alpha<\beta_{1}, \alpha<\beta_{2}$, and $\beta_{1}+\beta_{2} \leq 4 \alpha$, we have $P F_{2^{\alpha}}^{2}\left(2^{\beta_{1}}, 2^{\beta_{2}} ; 2,2 ; 2^{4 \alpha-\beta_{1}-\beta_{2}}\right) \neq \emptyset$. We will use Theorem 2.1 below to improve this result to cover all the cases $1<\beta_{i}$.

The purpose of this paper is to extend the methods of [13] (see also [5] and [18] for two dimensions and binary cases) in order to prove results about perfect factors in dimensions higher than two. Before we can state our main result we must first develop more notation and terminology.

We define $d$-dimensional vectors $\langle x\rangle^{d}=\langle x, \ldots, x\rangle$ and $\langle x\rangle^{\vec{\alpha}}=\left\langle x^{\alpha_{1}}, \ldots, x^{\alpha_{d}}\right\rangle$ for $\vec{\alpha}=$ $\left\langle\alpha_{1}, \ldots, \alpha_{d}\right\rangle$.

A fundamental block of $B$ is an array consisting of $r_{i}$ consecutive rows in the $i$ th dimension for each $i=1, \ldots, d$. Repeating such a block produces $B$. We will sometimes refer to a fundamental block of $B$ as $B$ when there is no chance of confusion. Thus, we will say that a matrix appears uniquely in an infinite periodic array if it appears uniquely in a fundamental block. In this case, addition on subscripts in the $i^{\text {th }}$ dimension is performed modulo $r_{i}$ and we think of $B$ toroidally. If $B=\left[b_{\vec{I}}\right]$ is any $d$-dimensional torus, the projection of $B$ along $i_{j}=h$ is the $(d-1)$-dimensional torus consisting of all entries $b_{\vec{I}}$ for which $i_{j}=h$.

As a necessary condition for perfect factors, we know that there are $k^{N_{d}} k$-ary $d$ dimensional matrices, where $N_{d}=\prod_{i=1}^{d} n_{i}$, and there are $t$ tori with $R_{d}$ positions each for a matrix to appear, where $R_{d}=\prod_{i=1}^{d} r_{i}$, and so we must have $t R_{d}=k^{N_{d}}$. Also, if ever some $r_{i}=n_{i}$, then the all 0's matrix appears more than once (at least $r_{i}>1$ times), and so we need $r_{i}>n_{i}$ for each $i$ as well. It is believed that these conditions are also sufficient, though again "small" cases may cause difficulty. Note that the conditions above determine $t$ from $N_{d}$ and $R_{d}$, hence the notation $P F_{k}^{d}(\vec{R} ; \vec{N} ; t)$ is somewhat redundent. We include $t$ for clarity.

Our main result is
Theorem 1.1. Let $k=\prod_{i=1}^{s} p_{i}^{\alpha_{i}}$ for primes $p_{i}$ and for $j \leq d$ suppose that $r_{j}=\prod_{i=1}^{s} p_{i}^{\beta_{i, j}}$ with each $p_{i}^{\beta_{i, j}}>2$. Further assume that for each $i \leq s$ there is a permutation $\sigma_{i}=\left(\sigma_{i, 1}, \ldots, \sigma_{i, d}\right)$ of $\{1, \ldots, d\}$ so that for each $l \leq d$ we have $\sum_{j=1}^{l} \beta_{i, \sigma_{i, j}} \leq \alpha_{i} 2^{l}$. Then $P F_{k}^{d}(\vec{R} ; \vec{N} ; t) \neq \emptyset$ for $\vec{R}=\left\langle r_{1}, \ldots, r_{d}\right\rangle, \vec{N}=\langle 2, \ldots, 2\rangle=\langle 2\rangle^{d}$, and $t=k^{N_{d}} / R_{d}$.

Observe that $t$ is determined by $\vec{R}$ and $\vec{N}$ as in the previous paragraph. The goal is to
determine, for given $d, k$, and $\vec{N}$, for which $\vec{R} P F_{k}^{d}(\vec{R} ; \vec{N} ; t)$ is nonempty, so the value of $t$ is really of no concern to us.

As an example, one can construct factors in $P F_{504}^{4}\left(2^{13} \cdot 3^{5} \cdot 7^{3}, 2^{5} \cdot 3^{14} \cdot 7^{1}, 2^{5} \cdot 3^{1} \cdot 7^{8}, 2^{13} \cdot 3^{7}\right.$. $\left.7^{2} ; 2,2,2,2 ; t\right)$ where $t=\left(2^{3} \cdot 3^{2} \cdot 7\right)^{2^{4}} /\left(2^{36} \cdot 3^{27} \cdot 7^{14}\right)=2^{12} \cdot 3^{5} \cdot 7^{2}$. The theorem comes from constructing perfect factors for each prime and then putting them together in a rather natural way. The role played by the permutation $\sigma$ in Theorem 1.1 is to transpose the factors from, say, $P F_{3^{2}}^{4}\left(3^{1}, 3^{5}, 3^{7}, 3^{14} ; 2,2,2,2 ; 3^{5}\right)$ to $P F_{3^{2}}^{4}\left(3^{5}, 3^{14}, 3^{1}, 3^{7} ; 2,2,2,2 ; 3^{5}\right)$. Likewise, we construct $P F_{2^{3}}^{4}\left(2^{5}, 2^{5}, 2^{13}, 2^{13} ; 2,2,2,2 ; 2^{12}\right)$ and $P F_{7}^{4}\left(7^{1}, 7^{2}, 7^{3}, 7^{8} ; 2,2,2,2 ; 7^{2}\right)$ from Lemma 3.3, below, and transpose them to $P F_{2^{3}}^{4}\left(2^{13}, 2^{5}, 2^{5}, 2^{13} ; 2,2,2,2 ; 2^{12}\right)$ and $P F_{7}^{4}\left(7^{3}, 7^{1}, 7^{8}, 7^{2} ; 2,2,2\right.$, $2 ; 7^{2}$ ), respectively. Then Theorem 2.3, below, will combine these three perfect factors into one.

What Theorem 1.1 doesn't yield are factors near the "diagonal"; that is, with the $r_{i}$ nearly equal. In fact, we cannot yet construct 3 -dimensional versions of totally square tori in $P F_{p}^{3}\left(\langle r\rangle^{d} ;\langle n\rangle^{d} ; 1\right)$ for prime $p$.

## 2. Building Blocks

Crucial tools in our inductive construction are found in the following theorems.
Theorem 2.1. ([17]) If $p^{\alpha}$ is a prime power and $n \geq 2$ with $n+1 \leq p^{\beta} \leq p^{\alpha n}$, then $P F_{p^{\alpha}}^{1}\left(p^{\beta} ; n ; p^{\alpha n-\beta}\right) \neq \emptyset$.

Let $B=\left[b_{\vec{I}}\right]$ be an infinite $d$-dimensional $k$-ary matrix, and let $B^{\prime}=\left[b_{\vec{I}}^{\prime}\right]$ be an infinite $d$-dimensional $k^{\prime}$-ary matrix. The term product $B \odot B^{\prime}$ is the $k k^{\prime}$-ary matrix with entry $\vec{I}$ given by $k^{\prime} b_{\vec{I}}+b_{\vec{I}}^{\prime}$. In [13] we find
Theorem 2.2. Let $\vec{R}=\left\langle r_{1}, \ldots, r_{d}\right\rangle$ and $\vec{R}^{\prime}=\left\langle r_{1}^{\prime}, \ldots, r_{d}^{\prime}\right\rangle$ have $\operatorname{gcd}\left(r_{j}, r_{j}^{\prime}\right)=1$ for all $j \leq d$. If $B \in P F_{k}^{d}(\vec{R} ; \vec{N} ; 1)$ and $B^{\prime} \in P F_{k^{\prime}}^{d}\left(\vec{R}^{\prime} ; \vec{N} ; 1\right)$, then $\left(B \odot B^{\prime}\right) \in P F_{k k^{\prime}}^{d}\left(\vec{R}^{\prime \prime} ; \vec{N}\right)$ with $\vec{R}^{\prime \prime}=\left\langle r_{1} r_{1}^{\prime}, \ldots, r_{d} r_{d}^{\prime}\right\rangle$.

It is straightforward to generalize Theorem 2.2 from De Bruijn tori to perfect factors. This yields
Theorem 2.3. Let $\vec{R}=\left\langle r_{1}, \ldots, r_{d}\right\rangle$ and $\vec{R}^{\prime}=\left\langle r_{1}^{\prime}, \ldots, r_{d}^{\prime}\right\rangle$ have $\operatorname{gcd}\left(r_{j}, r_{j}^{\prime}\right)=1$ for all $j \leq d$. If $\left\{B_{1}, \ldots, B_{t}\right\} \in P F_{k}^{d}(\vec{R} ; \vec{N} ; t)$ and $\left\{B_{1}^{\prime}, \ldots, B_{t^{\prime}}^{\prime}\right\} \in P F_{k^{\prime}}^{d}\left(\overrightarrow{R^{\prime}} ; \vec{N} ; t^{\prime}\right)$, then $\left\{B_{i} \odot B_{j}^{\prime}: 1 \leq i \leq\right.$ $\left.t, 1 \leq j \leq t^{\prime}\right\} \in P F_{k k^{\prime}}^{d}\left(\vec{R}^{\prime \prime} ; \vec{N} ; t^{\prime \prime}\right)$ with $\vec{R}^{\prime \prime}=\left\langle r_{1} r_{1}^{\prime}, \ldots, r_{d} r_{d}^{\prime}\right\rangle$ and $t^{\prime \prime}=t t^{\prime}$.

In the next section we use Theorem 2.1 and wait until the very end to use Theorem 2.3 in the proof of Theorem 1.1. We will also need several technical lemmas about perfect factors of order one such that the sum of the entries in each factor is zero modulo the base $k$. They will be used as a control on the resulting periods of our constructions.

Lemma 2.4. Let $p>2$ be a prime, $d \geq 1$, and $R_{d}=p^{\sum_{k=1}^{d} \beta_{k}}$. Then there is a partition $\left\{S_{1}, \ldots, S_{R_{d} / p}\right\}$ of the set of vectors $\prod_{k=1}^{d}\left[p^{\beta_{k}}\right]$ into sets of size $p$ such that, for each $i \leq R_{d} / p$,
the following holds. Let $S_{i}=\left\{V_{i, 1}, \ldots, V_{i, p}\right\}$ with $V_{i, j}=\left\langle v_{i, j, 1}, \ldots, v_{i, j, d}\right\rangle$. Then for each $k \leq d$ we have $\sum_{j=1}^{p} v_{i, j, k} \equiv 0 \quad\left(\bmod p^{\beta_{k}}\right)$.
Proof. We use induction. For $d=1$ we use the following factors $F_{h, i}$ (for the $S_{j}$ ), where $i=0,1, \ldots, p-1$ and $h=0,1, \ldots p^{\beta_{1}-2}-1$.

$$
F_{h, i}=\left\{h p^{2}+i p+j \mid j=0,1, \ldots, p-2\right\} \cup\left\{p^{\beta_{1}}-\binom{p-1}{2}-i p(p-1)-h p^{2}(p-1)\right\}
$$

It is easy to see that these factors partition $\left[p_{1}^{\beta}\right]$ since since the former set making up each $F_{h, i}$ takes cares of those integers congruent to $0,1, \ldots, p-2$ modulo $p$ and the latter set takes care of those congruent to $p-1$ modulo $p$. The sum of the terms in $F_{h, i}$ is $\left(\sum_{j=0}^{p-2}\left(h p^{2}+i p+\right.\right.$ $j))+p^{\beta_{1}}-\binom{p-1}{2}-i p(p-1)-h p^{2}(p-1)=p^{\beta_{1}}$ which is congruent to 0 modulo $p_{1}^{\beta}$.

For $d>1$ we use the previous construction from the case $d-1$ and append a $d^{\text {th }}$ coordinate onto every vector in the following way. Given a set $S_{i}=\left\{\left\langle v_{i, 1,1}, \ldots, v_{i, 1, d-1}\right\rangle, \ldots,\left\langle v_{i, p, 1}\right.\right.$, $\left.\left.\ldots, v_{i, p, d-1}\right\rangle\right\}$ from the $(d-1)$ - construction, and $x_{j}=\left\{x_{1}, x_{2}, \ldots x_{p}\right\} \in P F_{p^{\beta_{d}}}^{1}\left(p ; 1 ; p^{\beta_{d}-1}\right)$ (from the case $d=1$ ), we construct the sets $S_{i, j, 0}, S_{i, j, 1}, \ldots, S_{i, j, p-1}$ where $S_{i, j, k}=\left\{\left\langle v_{i, 1,1}, \ldots\right.\right.$, $\left.\left.v_{i, 1, d-1}, x_{1+k}\right\rangle, \ldots,\left\langle v_{i, p, 1}, \ldots, v_{i, p, d-1}, x_{p+k}\right\rangle\right\}$ and where the subscripts on the $d^{t h}$ coordinate are taken $\bmod p$. This yields the $p\left(p^{\beta_{d}-1}\right)\left(R_{d-1} / p\right)=R_{d} / p$ sets with the necessary modular properties.

Lemma 2.4'. Let $p=2, d \geq 2,2 \leq \beta_{1} \leq \ldots \leq \beta_{d}$, and $R_{d}=2^{\sum_{k=1}^{d} \beta_{k}}$. Then there is a partition $\left\{S_{1}, \ldots, S_{R_{d} / 4}\right\}$ of the set of vectors $\prod_{k=1}^{d}\left[2^{\beta_{k}}\right]$ into sets of size 4 such that, for each $i \leq R_{d} / 4$, the following holds. Let $S_{i}=\left\{V_{i, 1}, \ldots, V_{i, 4}\right\}$ with $V_{i, j}=\left\langle v_{i, j, 1}, \ldots, v_{i, j, d}\right\rangle$. Then for each $k \leq d$ we have $\sum_{j=1}^{4} v_{i, j, k} \equiv 0\left(\bmod 2^{\beta_{k}}\right)$.
Proof. We use induction. For $d=2$ we use the following matching to figure the set of $k^{\text {th }}$ coordinates. Each $0<x_{k}<2^{\beta_{k}-1}$ is matched with $y_{k}=2^{\beta_{k}}-x_{k}$, and $x_{k}=0$ is matched with $y_{k}=2^{\beta_{k}-1}$. To construct a particular set $S_{i}=\left\{\left\langle v_{i, 1,1}, v_{i, 1,2}\right\rangle, \ldots,\left\langle v_{i, 4,1}, v_{i, 4,2}\right\rangle\right\}$ we choose one of the $2^{\beta_{1}-1}$ matches $\left(x_{1}, y_{1}\right)$ and one of the $2^{\beta_{2}-1}$ matches $\left(x_{2}, y_{2}\right)$ to form the set $\left\{\left\langle x_{1}, x_{2}\right\rangle,\left\langle x_{1}, y_{2}\right\rangle,\left\langle y_{1}, x_{2}\right\rangle,\left\langle y_{1}, y_{2}\right\rangle\right\}$. This produces $\left(2^{\beta_{1}-1}\right)\left(2^{/ b_{2}-1}\right)=R_{2} / 4$ sets with the necessary modular properties.

For $d>2$ we use the previous construction from the case $d-1$ and append a $d^{t h}$ coordinate onto every vector in the following way. As above, we will use the set of matches $\left\{\left(x_{d}, y_{d}\right)\right\}$, defined analogously using $\beta_{d}$. Given a set $S_{i}=\left\{\left\langle v_{i, 1,1}, \ldots, v_{i, 1, d-1}\right\rangle, \ldots,\left\langle v_{i, 4,1}, \ldots\right.\right.$, $\left.\left.v_{i, 4, d-1}\right\rangle\right\}$ from the $(d-1)$ - construction, and given a particular match $\left(x_{d}, y_{d}\right)$, we construct the sets $S_{i}^{\prime}$ and $S_{i}^{\prime \prime}$ as follows. $S_{i}^{\prime}=\left\{\left\langle v_{i, 1,1}, \ldots, v_{i, 1, d-1}, x_{d}\right\rangle,\left\langle v_{i, 2,1}, \ldots, v_{i, 2, d-1}, x_{d}\right\rangle\right.$, $\left.\left\langle v_{i, 3,1}, \ldots, v_{i, 3, d-1}, y_{d}\right\rangle,\left\langle v_{i, 4,1}, \ldots, v_{i, 4, d-1}, y_{d}\right\rangle\right\}$ and $S_{i}^{\prime \prime}$ switches the roles of $x_{d}$ and $y_{d}$. This yields $2\left(2^{\beta_{d}-1}\right)\left(R_{d-1} / 4\right)=R_{d} / 4$ sets with the necessary modular properties.

Corollary 2.5. Let $p>2$ be a prime, $d \geq 1$, and $R_{d}=p^{\sum_{k=1}^{d} \beta_{k}}$. Then for any integer $1 \leq m \leq \sum_{k=1}^{d} \beta_{k}$ there is a partition $\left\{S_{1}, \ldots, S_{R_{d} / p^{m}}\right\}$ of the set of vectors $\prod_{k=1}^{d}\left[p^{\beta_{k}}\right]$ into sets of size $p^{m}$ such that, for each $i \leq R_{d} / p^{m}$, the following holds. Let $S_{i}=\left\{V_{i, 1}, \ldots, V_{i, p^{m}}\right\}$ with $V_{i, j}=\left\langle v_{i, j, 1}, \ldots, v_{i, j, d}\right\rangle$. Then for each $k \leq d$ we have $\sum_{j=1}^{p^{m}} v_{i, j, k} \equiv 0\left(\bmod p^{\beta_{k}}\right)$.
Proof. Concatenate as many of the sequences from Lemma 2.4 as needed.
Corollary 2.5'. Let $p=2, d \geq 2,2 \leq \beta_{1} \leq \ldots \leq \beta_{d}$, and $R_{d}=2^{\sum_{k=1}^{d} \beta_{k}}$. Then for any integer $2 \leq m \leq \sum_{k=1}^{d} \beta_{k}$ there is a partition $\left\{S_{1}, \ldots, S_{R_{d} / 2^{m}}\right\}$ of the set of vectors $\prod_{k=1}^{d}\left[2^{\beta_{k}}\right]$ into sets of size $2^{m}$ such that, for each $i \leq R_{d} / 2^{m}$, the following holds. Let $S_{i}=$ $\left\{V_{i, 1}, \ldots, V_{i, 2^{m}}\right\}$ with $V_{i, j}=\left\langle v_{i, j, 1}, \ldots, v_{i, j, d}\right\rangle$. Then for each $k \leq d$ we have $\sum_{j=1}^{2^{m}} v_{i, j, k} \equiv 0$ $\left(\bmod 2^{\beta_{k}}\right)$.
Proof. Concatenate as many of the sequences from Lemma $2.4^{\prime}$ as needed.

## 3. Proof of Theorem 1.1

Lemma 3.1. Let $t_{d}=p^{\alpha 2^{d}-\sum_{i=1}^{d} \beta_{i}}$ and $t_{d+1}=p^{\alpha 2^{d+1}-\sum_{i=1}^{d+1} \beta_{i}}$. If $P F_{p^{\alpha}}^{d}\left(\langle p\rangle^{\vec{\beta}} ;\langle 2\rangle^{d} ; t_{d}\right) \neq \emptyset$ and $\beta_{d+1} \leq \alpha 2^{d+1}-\sum_{k=1}^{d} \beta_{k}$ (so that $\sum_{k=1}^{d+1} \beta_{k} \leq \alpha 2^{d+1}$; i.e., $R_{d+1} \mid p^{\alpha N_{d+1}}$ ), then $P F_{p^{\alpha}}^{d+1}\left(\langle p\rangle^{\vec{\beta}}, p^{\beta_{d+1}}\right.$; $\left.\langle 2\rangle^{d+1} ; t_{d+1}\right) \neq \emptyset$.

We note that many of the arguments below can be made for arbitrary $\vec{N}$ (with the modification $\beta_{d+1} \leq \alpha N_{d+1}-\sum_{k=1}^{d} \beta_{k}$ in the hypothesis), though we lose the ability later on to transpose freely the factors produced. Also, the statement for $\vec{N}=\langle n\rangle^{d}$ becomes more cumbersome, and so we aim here for clarity rather than generality. We also note that in the application of Lemma 3.1 to Lemma 3.3 which follows, it may be assumed that $\beta_{i} \leq \beta_{i+1}$ for each $i \leq d$, since reordering in this way will not violate the hypothesis of Lemma 3.1 (reordering in nonincreasing fashion, however, may at times violate the hypothesis).
Proof. Basically, the strategy is based on ideas and techniques found in [5,6,11,16]. However, since we are constructing perfect factors rather than De Bruijn tori (perfect maps), there is some added difficulty in ensuring that the arrays have the proper period. Given any $p^{\alpha}$-ary $(d+1)$-dimensional matrix $M$ of size $\langle 2\rangle^{d+1}$ we see that its projection along $i_{d+1}=i$ is a $d$-dimensional matrix $M_{i}$, which occurs in a unique $A_{u(i)} \in \mathcal{A}$, for $\mathcal{A} \in P F_{p^{\alpha}}^{d}\left(\langle p\rangle^{\vec{\beta}} ;\langle 2\rangle^{d} ; t_{d}\right)$, in the unique position $\vec{J}\left(A_{u(i)}\right)$. So the matrix $M$ can be partially encoded by the ordered pair $(u(0), u(1))$, since $i \in\{0,1\}$, and we are interested in using a 1-dimensional perfect factor $\mathcal{U}$ for pairs with base $|\mathcal{A}|=t_{d}=p^{\alpha N_{d}} / R_{d}$ to locate $M$. The rest of the encoding comes from the positions $\vec{J}\left(A_{u(x)}\right)$. The difference $\vec{J}\left(A_{u(1)}\right)-\vec{J}\left(A_{u(0)}\right)$ is a vector $\vec{S}=\left\langle s_{1}, s_{2}, \ldots, s_{d}\right\rangle$ where $s_{i} \in\left\{0,1, \ldots, p^{\beta-1}\right\}$. This vector $\vec{S}$ can be assigned an integer via any bijection $g: \prod_{k=1}^{d}\left[p^{\beta_{k}}\right] \longrightarrow\left[\prod_{k=1}^{d} p^{\beta_{k}}\right]=\left[R_{d}\right]$, and so we are also interested in using a 1-dimensional perfect factor $\mathcal{V}$ for singletons with base $R_{d}$ to locate $M$.

To show that the following constructions are indeed a perfect factors, we must show
that each matrix $M$ can be found uniquely and that the arrays are periodic with the correct period. Uniqueness will be shown by noting that the pair $(u(0), u(1))$ appears uniquely in the same position as the shift $\vec{J}\left(A_{u(1)}\right)-\vec{J}\left(A_{u(0)}\right)$ in the constructions below.

What remains in the proof is to construct sequences which will match up the pairs $(u(0), u(1))$ with the images $x_{i}$ of the shift vectors $\vec{S}_{i}$. There will be four cases, based on whether $r_{d+1} \mid\left(t_{d}\right)^{2}$ or $\left(t_{d}\right)^{2} \mid r_{d+1}$ and whether $r_{d+1} \mid R_{d}$ or $R_{d} \mid r_{d+1}$. The perfect factors $\mathcal{U}$ and $\mathcal{V}$ will come from Theorem 2.1 and from Corollaries 2.5 and $2.5^{\prime}$, respectively.

Case 1: $r_{d+1} \mid\left(t_{d}\right)^{2}$ and $r_{d+1} \mid R_{d}$. Given any $U_{i}=\left(u_{i, 0}, u_{i, 1}, \ldots\right) \in \mathcal{U}=\left\{U_{1}, U_{2}, \ldots\right\} \in$ $P F_{t_{d}}^{1}\left(r_{d+1} ; 2 ;\left(t_{d}\right)^{2} / r_{d+1}\right)$ and $V_{j}=\left(v_{j, 0}, v_{j, 1}, \ldots\right) \in \mathcal{V}=\left\{V_{1}, V_{2}, \ldots\right\} \in P F_{R_{d}}^{1}\left(r_{d+1} ; 1 ; R_{d} / r_{d+1}\right)$ we construct $r_{d+1}$ periodic sequences $W_{0}\left(U_{i}, V_{j}\right), \ldots, W_{r_{d+1}-1}\left(U_{i}, V_{j}\right)$, each of period $r_{d+1}$, with the property that the $k^{t h}$ entry $W_{l}\left(U_{i}, V_{j}\right)_{k}$ of $W_{l}\left(U_{i}, V_{j}\right)$ is the ordered pair $\left(u_{i, k}, v_{j, k+l}\right)$. Clearly, for every $(a, b) \in\left[t_{d}\right]^{2}, c \in\left[R_{d}\right]$, there are unique $i, j, k$ and $l$ such that $W_{l}\left(U_{i}, V_{j}\right)_{k}=$ $(a, c), W_{l}\left(U_{i}, V_{j}\right)_{k+1}=(b, \cdot)$, and $k<r_{d+1}$. Thus $\mathcal{W}=\left\{W_{l}\left(U_{i}, V_{j}\right): i \in\left[\left(t_{d}\right)^{2} / r_{d+1}\right], j \in\right.$ $\left.\left[R_{d} / r_{d+1}\right], l \in\left[r_{d+1}\right]\right\}$ forms an encoding of the $|\mathcal{W}|=\left(\left(t_{d}\right)^{2} / r_{d+1}\right) \cdot\left(R_{d} / r_{d+1}\right) \cdot r_{d+1}=$ $\left(t_{d}\right)^{2} R_{d} / r_{d+1}=t_{d+1}$ factors in the family $\mathcal{A}^{\prime} \in P F_{p^{\alpha}}^{d+1}\left(\langle p\rangle^{\vec{\beta}}, p^{\beta_{d+1}} ;\langle 2\rangle^{d+1} ; t_{d+1}\right)$ generated by $\mathcal{A} \in P F_{p^{\alpha}}^{d}\left(\langle p\rangle^{\vec{\beta}} ;\langle 2\rangle^{d} ; t_{d}\right)$.

Case 2: $r_{d+1} \mid\left(t_{d}\right)^{2}$ and $R_{d} \mid r_{d+1} . ~ \mathcal{U}$ is as in case 1, but now we take $\mathcal{V}=\{V\} \in$ $P F_{R_{d}}^{1}\left(R_{d} ; 1 ; 1\right)$ and, for each $i$, construct $R_{d}$ periodic sequences $W_{l}\left(U_{i}, V\right)$, defined as before, with $i \in\left[\left(t_{d}\right)^{2} / r_{d+1}\right]$ and $l \in\left[R_{d}\right]$. As before, we get $|\mathcal{W}|=\left(t_{d}\right)^{2} R_{d} / r_{d+1}=t_{d+1}$ sequences to encode the factors in $\mathcal{A}^{\prime}$.

Case 3: $\left(t_{d}\right)^{2} \mid r_{d+1}$ and $r_{d+1} \mid R_{d} . \mathcal{V}$ is as in case 1 , but $\mathcal{U}=\{U\} \in P F_{t_{d}}^{1}\left(\left(t_{d}\right)^{2} ; 2 ; 1\right)$ and for each $j$ we construct $\left(t_{d}\right)^{2}$ periodic sequences $W_{l}\left(U, V_{j}\right)$, defined above, with $j \in\left[R_{d} / r_{d+1}\right]$ and $l \in\left[\left(t_{d}\right)^{2}\right]$. Again, $|\mathcal{W}|=t_{d+1}$.

Case 4: $\left(t_{d}\right)^{2} \mid r_{d+1}$ and $R_{d} \mid r_{d+1}$ (and $\left.r_{d+1} \Lambda R_{d}\right) . \mathcal{V}$ is as in case 2 , but now we use $\mathcal{U} \in P F_{t_{d}}^{1}\left(r_{d+1} / R_{d} ; 2 ;\left(t_{d}\right)^{2} R_{d} / r_{d+1}\right)$. (See below for the case $r_{d+1} / R_{d}=2$, in which case such a $\mathcal{U}$ does not exist.) We use a different technique here, first used in [6] and again in [11]. Let $V=\left(v_{0}, v_{1}, \ldots, v_{R_{d}-1}, v_{0}, v_{1}, \ldots\right)$. Denote by $v_{0}^{x}$ the sequence $\left(v_{0}, v_{0}, \ldots, v_{0}\right)$ of length $x$, let $V^{\prime}=\left(v_{1}, \ldots, v_{R_{d}-1}\right)$ and denote by $\left(V^{\prime}\right)^{x}$ the concatenated sequence $V^{\prime} V^{\prime} \cdots V^{\prime}$ of $V^{\prime}$ with itself $x$ times. Now let $V^{\prime \prime}=v_{0}^{x}\left(V^{\prime}\right)^{x}=\left(v_{0}^{\prime \prime}, v_{1}^{\prime \prime}, \ldots, v_{r_{d+1}}^{\prime \prime}\right)$, with $x=r_{d+1} / R_{d}$, and for each $i$ construct the sequence $W\left(U_{i}, V^{\prime \prime}\right)$, of period $r_{d+1}$ defined by $W\left(U_{i}, V^{\prime \prime}\right)_{k}=$ $\left(u_{i, k}, v_{k}^{\prime \prime} \quad\left(\bmod R_{d}\right)\right.$. It is not difficult $([6,11])$ to see that for every $(a, b) \in\left[t_{d}\right]^{2}, c \in\left[R_{d}\right]$, there are unique $i$ and $k$ such that $W\left(U_{i}, V^{\prime \prime}\right)_{k}=(a, c), W\left(U_{i}, V^{\prime \prime}\right)_{k+1}=(b, \cdot)$, and $k<r_{d+1}$. Also, $|\mathcal{W}|=\left(t_{d}\right)^{2} R_{d} / r_{d+1}=t_{d+1}$, completing the proof of Lemma 3.1 when $r_{d+1} / R_{d} \neq 2$.

If $r_{d+1} / R_{d}=2$ take $U^{\prime} \in P F_{t_{d}}^{1}\left(\left(t_{d}\right)^{2} ; 2 ; 1\right)$ and concatenate $r_{d+1} /\left(t_{d}\right)^{2}$ copies of $U^{\prime}$ to get $U$ (with length $r_{d+1}$ ). Take $V=\left(v_{0}, v_{1}, \ldots, v_{R_{d}-1}\right) \in P F_{R_{d}}^{1}\left(R_{d} ; 1 ; 1\right)$. For $j=$ $1,2, \ldots,\left(t_{d}\right)^{2} R_{d} / r_{d+1}=t_{d+1}$ let $V_{j}$ have $k^{t h}$ entry $v_{2 j+k}$ if $0 \leq k<R_{d}$ and $v_{2 j+1+\left(k-R_{d}\right)}$
if $R_{d} \leq k<2 R_{d}$. Now for $0 \leq j<t_{d+1}$, let $W\left(U, V_{j}\right)$ have $k^{t h}$ entry given by the ordered pair of $k^{t h}$ entries from $U$ and $V_{j}$. Checking that this encoding has the correct uniqueness and modular properties is straightforward.

Observe that in extending this to $n_{i}>2$, the only difficulty in the above proof involves the last paragraph of case 4 . Also, analogues of Corollaries 2.5 and $2.5^{\prime}$ are needed. However, these can be obtained as in the proof of Corollary 2.5 using results from [17].
Lemma 3.2. For all $\beta_{1} \geq 2, \beta_{2} \geq 2$, and $\alpha$ with $\beta_{1}+\beta_{2} \leq 4 \alpha$ we have $P F_{2^{\alpha}}^{2}\left(2^{\beta_{1}}, 2^{\beta_{2}} ; 2,2\right.$; $\left.2^{4 \alpha-\beta_{1}-\beta_{2}}\right) \neq \emptyset$.
Proof. We assume that $\beta_{1} \leq \beta_{2}$, otherwise we would simply switch the roles of $\beta_{1}$ and $\beta_{2}$ and transpose the result of what follows. This and the hypotheses imply that $\beta_{1} \leq 2 \alpha$ so that $P F_{2^{\alpha}}^{1}\left(2^{\beta_{1}} ; 2 ; 2^{2 \alpha-\beta_{1}}\right) \neq \emptyset$ by Theorem 2.1. Let $\mathcal{U}=\left\{U_{1}, \ldots, U_{2^{2 \alpha-\beta_{1}}}\right\}$ be such a perfect factor.

Consider first the case that $2 \beta_{1}+\beta_{2} \leq 4 \alpha$. Then $\beta_{2} \leq 2\left(2 \alpha-\beta_{1}\right)$ so $P F_{2^{2 \alpha-\beta_{1}}}^{1}\left(2^{\beta_{2}} ; 2\right.$; $\left.2^{4 \alpha-2 \beta_{1}-\beta_{2}}\right) \neq \emptyset$ by Theorem 2.1. Let $\mathcal{V}=\left\{V_{1}, \ldots, V_{2^{4 \alpha-2 \beta_{1}-\beta_{2}}}\right\}$ be such a perfect factor. If $(x, y)$ is a particular pair of adjacent digits in some $V_{i}$ then our encoding will tell us to juxtapose $U_{x}$ and $U_{y}$ as columns in a matrix. In order to construct a two-dimensional perfect factor we need that every ordered pair $\left(U_{x}, U_{y}\right)$ appears exactly $2^{\beta_{1}}$ times, once with each possible shift of $U_{y}$ with respect to $U_{x}$. In this case we use the sequences $S_{x}=(x)^{2^{\beta_{2}}}$, for each $x \in\left[2^{\beta_{1}}\right]$, each of which sums to $0\left(\bmod 2^{\beta_{1}}\right)$ since $\beta_{1} \leq \beta_{2}$. Each $S_{x}$ gets paired with each $V_{i}$ to create the $\left(2^{\beta_{1}}\right)\left(2^{4 \alpha-2 \beta_{1}-\beta_{2}}\right)=2^{4 \alpha-\beta_{1}-\beta_{2}}$ matrices in the factor required by the theorem.

Consider, on the other hand, the case that $2 \beta_{1}+\beta_{2}>4 \alpha$, and suppose that $\beta_{1}<2 \alpha$. Use $\mathcal{U}$ as above and take $\mathcal{V}=\{V\} \in P F_{2^{2 \alpha-\beta_{1}}}^{1}\left(2^{4 \alpha-2 \beta_{1}} ; 2 ; 1\right)$. Now we denote by $(a, b)^{k}$ the sequence $(a, b, a, b, \ldots, a, b)$ of length $2 k$ and, for $x \in\left[2^{\beta_{1}}\right]$, define the shift sequences $S_{x}=\left(x, 2^{\beta_{1}}-x\right)^{2^{\beta_{1}-1}}$, each of which sums to $0\left(\bmod 2^{\beta_{1}}\right)$. We partition $\left[2^{\beta_{1}}\right]$ into index sets $I_{1}, \ldots, I_{2^{4 \alpha-\beta_{1}-\beta_{2}}}$, of size $2^{2 \beta_{1}+\beta_{2}-4 \alpha}$ each, and for each $I_{j}=\left\{i(j, 1), \ldots, i\left(j, 2^{2 \beta_{1}+\beta_{2}-4 \alpha}\right)\right\}$ we concatenate the sequences $S_{i(j, 1)}, \ldots, S_{i\left(j, 2^{2 \beta_{1}+\beta_{2}-4 \alpha}\right)}$, to form the sequence $S(j)$. Form the sequence $V^{2 \beta_{1}+\beta_{2}-4 \alpha}$ by concatenating $V$ with itself $2^{2 \beta_{1}+\beta_{2}-4 \alpha}$ times, and then pair each $S(j)$ with $V^{2^{2 \beta_{1}+\beta_{2}-4 \alpha}}$. As above, this produces the necessary $2^{4 \alpha-\beta_{1}-\beta_{2}}$ matrices for the factor we need.

Lastly, consider the case $\beta_{1}=2 \alpha$, which means that $\beta_{2}=2 \alpha$ as well since $\beta_{1}+$ $\beta_{2} \leq 4 \alpha$. Thus we want to show that we can find a totally square De Bruijn torus in $P F_{2^{\alpha}}^{2}\left(2^{2 \alpha}, 2^{2 \alpha} ; 2,2,1\right)$. But this set of tori has been shown to be nonempty in $[12,14]$, and this completes the proof of Lemma 3.2.
Lemma 3.3. Let $p^{\alpha}$ be a prime power, for $j \leq d$ let $r_{j}=p^{\beta_{j}}>2$ and suppose that for each $l \leq d$ we have $\sum_{j=1}^{l} \beta_{j} \leq \alpha 2^{l}$. Then $P F_{p^{\alpha}}^{d}\left(\vec{R} ;\langle 2\rangle^{d} ; t\right) \neq \emptyset$, where $\vec{R}=\left\langle r_{1}, \ldots, r_{d}\right\rangle$ and
$t=p^{\alpha 2^{d}-\sum_{j=1}^{d} \beta_{j}}$.
Proof. We will use induction on $d$. For the base cases, when $d=1$ we have $P F_{p^{\alpha}}^{1}\left(p^{\beta} ; 2 ; p^{2 \alpha-\beta}\right)$ $\neq \emptyset$ from Theorem 2.1. If $p=2$ then we also need $d=2$ as a base case. For this we have $P F_{2^{\alpha}}^{2}\left(2^{\beta_{1}}, 2^{\beta_{2}} ; 2,2 ; 2^{4 \alpha-\beta_{1}-\beta_{2}}\right) \neq \emptyset$ from Lemma 3.2. For $d>1$ (or $d>2$ if $p=2$ ) the hypotheses for case $d$ imply those for case $d-1$, which in turn imply those of Lemma 3.1, which finishes the proof.
Proof of Theorem 1.1. Use Lemma 3.3 followed by Theorem 2.3.
